## Resources

<https://goalkicker.com/BashBook/>

<https://goalkicker.com/LinuxBook/>

[Linux Tutorial | A Basic Guide to Linux For Beginners \(educba.com\)](#)

<https://www.educba.com/software-development/software-development-tutorials/linux-tutorial/>

## apt – Advanced Packaging Tool

<https://itsfoss.com/apt-command-guide/>

**sudo apt update** Updates the package database.

**sudo list –upgradable** Lists all packages which may be upgraded.

**sudo apt upgrade** Upgrades the packages.

**sudo apt full-upgrade** Not only upgrades but removes unnecessary packages.

`sudo apt update && sudo apt upgrade -y`

Runs update and upgrade in tandem.

`sudo apt install <package_name>` Install a new package.

`sudo apt install <package_1> <package_2> <package_3>`

Install multiple packages.

`sudo apt reinstall <package_name>` Reinstall packages.

**\*\* All The Way! \*\***

`sudo apt update && sudo apt full-upgrade -y`

Remove Unused Packages

**Sudo apt autoremove or sudo apt-get autoremove**

Finds and removes those packages which are unused dependencies and not needed.

What if you run apt install on an already installed package?

No need to worry. This will just look into the database and if a newer version is found, it will upgrade the installed package to the newer one. So, no harm is done by using it, unless you don't want it to be upgraded.

Install Without Upgrading!

`sudo apt install <package_name> --no-upgrade`

Install without upgrading.

If for some reason you want to install a package, but don't want to upgrade, if it is already installed. In that case, you can use the option **–no-upgrade** .

## Uninstalling a Package

[How to Uninstall Software in Linux With Apt \(makeuseof.com\)](https://makeuseof.com/how-to-uninstall-software-in-linux-with-apt/)

### **sudo apt-get remove nameofpackage**

This will remove package but keep your settings and configurations.

### **sudo apt-get purge nameofpackage**

This will remove the package plus remove your settings and configurations.

## Terminal Command Prompt

# Means 'Root' user.

\$ Means everybody else.

~ Means Home Directory.

## System Info for Linux Distribution

**lsb\_release** Must be installed.

apt-get update && apt-get install -y lsb-release && apt-get clean all

**lsb\_release -a** All available system information.

**hostname** Displays the host name or machine name.

**hostnamectl** Displays the host name plus additional information.

**uname** Print system information.

**uname -s** Print kernel name of system.

**sudo lshw** Hardware info on components: cpu, disks, memory, usb controllers etc.

**sudo lshw -short** Summary hardware information.

**lscpu** Shows CPU architecture information.

**lsblk** Shows storage device info for hard disks, flash drives etc.

**lsblk -a** All storage device info.

**df** disk usage

**df -m** display disk usage in MB (mega-bytes).

## Change the Hostname

First query and display the hostname:

```
hostname <Enter>
```

If you choose to set a new hostname, use the following command.

The hostname commands set the host name using the following syntax. Please note that only the super-user / root can change the names. To switch to the root user by typing su – and entering the root password, when prompted.

```
# hostnamectl set-hostname laptop.nixcraft.in
```

You need to edit /etc/hostname or /etc/sysconfig/network file to set hostname permanently.

Read the Manual Pages before you do this.

```
man hostnamectl
```

Reference:

<https://www.howtogeek.com/197934/how-to-change-your-hostname-computer-name-on-ubuntu-linux>

Host names can only contain letters (a through z), digits (0 through 9), and the hyphen character ( – ), and the period character ( . ). A hostname must begin and end with a letter or number — not a hyphen or period. Letters are also case-insensitive, so “COMPUTER” is equivalent to “computer.” The hostname must be between 2 and 63 characters long, although you’ll probably find shorter hostnames more convenient.

### 1. Edit Your /etc/hostname File

```
sudo subl /etc/hostname
```

Replace the old hostname with the new hostname.

### 2. Edit Your /etc/hosts File

```
sudo subl /etc/hosts
```

The old hostname will be styled like this:

```
127.0.1.1 your-old-hostname
```

Simply replace the old host name but do not disturb the number (127.0.1.1 in this example).

## Change Your Hostname Immediately

If you wish to activate changes to the hostname immediately, run this command:

```
sudo hostname your-new-hostname
```

To complete the hostname change and make it permanent, log off and log back on again.

## Switch to Root User

[Root User in Ubuntu- Important Things You Should Know](#)

```
sudo -i    Become Root User. You must enter your password.
```

## Change User Data

Change User Data with *chfn*, *usermod*, and *finger*

[How to Change User Data With chfn and usermod on Linux \(howtogeek.com\)](#)

Install finger:

```
sudo apt install finger
```

**finger mike -l** (-l is L) Lists all the GECOS information about account **mike**.

**sudo chfn -f Ubuntu03-Mike mike** Changes the full name in the GECOS field for account 'mike'. DO NOT put any punctuation marks around the new name (Example: Ubuntu03-Mike). No quotation mark and no tick marks.

## Create Groups in Linux

In Linux, groups are used to organize and administer user accounts. The primary purpose of groups is to define a set of privileges such as reading, writing, or executing permission for a given resource that can be shared among the users within the group.

### groupadd Command Syntax

The general syntax for the groupadd command is as follows:

```
groupadd [OPTIONS] GROUPNAME
```

Only the root or a user with sudo privileges can create new groups.

When invoked, groupadd creates a new group using the options specified on the command line plus the default values specified in the /etc/login.defs file.

For example, to create a new group named mygroup you would run:

```
groupadd mygroup
```

The command adds an entry for the new group to the /etc/group and /etc/gshadow files.

Once the group is created, you can start adding users to the group .

If the group with the same name already exist, the system will print an error message like the following:

```
groupadd: group 'mygroup' already exists
```

To suppress the error message if the group exist and to make the command exit successfully, use the -f (--force) option:

```
groupadd -f mygroup
```

## Create Users

<https://www.lifewire.com/create-users-useradd-command-3572157>

<https://www.thegeekdiary.com/beginners-guide-to-user-and-group-administration-in-linux>

To add a new user: Use the command:

```
useradd test ("test" is the new user's name)
```

Use `sudo useradd test` if you lack the proper privileges.

```
sudo useradd test
```

To create a user with a home directory: Use:

```
sudo useradd -m test
```

or

```
sudo useradd -m -d /test test # change the default directory
```

To set a user's password, Use:

```
passwd test
```

To switch users, use the command:

```
su - test
```

## Assign Users to Groups

<https://www.howtogeek.com/50787/add-a-user-to-a-group-or-second-group-on-linux/>

### Add a User With gpasswd

<https://unix.stackexchange.com/questions/29570/how-do-i-remove-a-user-from-a-group>

Usage: gpasswd [option] GROUP

#### Options:

- a, --add USER                add USER to GROUP
- d, --delete USER            remove USER from GROUP
- h, --help                    display this help message and exit
- Q, --root CHROOT\_DIR        directory to chroot into
- r, --remove-password        remove the GROUP's password
- R, --restrict                restrict access to GROUP to its members
- M, --members USER,...       set the list of members of GROUP
- A, --administrators ADMIN,...  
                              set the list of administrators for GROUP

### Add an Existing User Account to a Group

To add an existing user account to a group on your system, use the `usermod` command, replacing `examplegroup` with the name of the group you want to add the user to and `exampleusername` with the name of the user you want to add.

```
usermod -a -G examplegroup exampleusername
```

For example, to add the user `geek` to the group `sudo`, use the following command:

```
usermod -a -G sudo geek
```

## Change a User's Primary Group

While a user account can be part of multiple groups, one of the groups is always the “primary group” and the others are “secondary groups”. The user’s login process and files and folders the user creates will be assigned to the primary group.

To change the primary group a user is assigned to, run the `usermod` command, replacing `examplegroup` with the name of the group you want to be the primary and `exampleusername` with the name of the user account.

```
usermod -g groupname username
```

Note the `-g` here. When you use a lowercase `g`, you assign a primary group. When you use an uppercase `-G`, as above, you assign a new secondary group.

## View the Groups a User Account is Assigned To

To view the groups the current user account is assigned to, run the `groups` command. You’ll see a list of groups.

```
groups
```

To view the numerical IDs associated with each group, run the `id` command instead:

```
id
```

To view the groups another user account is assigned to, run the `groups` command and specify the name of the user account.

```
groups exampleusername
```

You can also view the numerical IDs associated with each group by running the `id` command and specifying a username.

```
id exampleusername
```

The first group in the `groups` list or the group shown after “`gid=`” in the `id` list is the user account’s primary group. The other groups are the secondary groups. So, in the screenshot below, the user account’s primary group is `example`.

## Create a New User and Assign a Group in One Command

You may sometimes want to create a new user account that has access to a particular resource or directory, like a new FTP user. You can specify the groups a user account will be assigned to while creating the user account with the **useradd** command, like so:

```
useradd -G examplegroup exampleusername
```

For example, to create a new user account named **jsmith** and assign that account to the ftp group, you'd run:

```
useradd -G ftp jsmith
```

You'll want to assign a password for that user afterwards, of course:

```
passwd jsmith
```

## Add a User to Multiple Groups

While assigning the secondary groups to a user account, you can easily assign multiple groups at once by separating the list with a comma.

```
usermod -a -G group1,group2,group3 exampleusername
```

For example, to add the user named geek to the ftp, sudo, and example groups, you'd run:

```
usermod -a -G ftp,sudo,example geek
```

You can specify as many groups as you like—just separate them all with a comma.

## View All Groups on the System

If you want to view a list of all groups on your system, you can use the `getent` command:

```
getent group
```

This output will also show you which user accounts are members of which groups.

## Add User to Admin Group

Add 'Marlena' to the sudo or admin group.

```
usermod -aG sudo Marlena
```

## Delete A User from a Group

### Delete a User from Group With gpasswd

<https://unix.stackexchange.com/questions/29570/how-do-i-remove-a-user-from-a-group>

Usage: gpasswd [option] GROUP

#### Options:

- a, --add USER                add USER to GROUP
- d, --delete USER            remove USER from GROUP
- h, --help                    display this help message and exit
- Q, --root CHROOT\_DIR        directory to chroot into
- r, --remove-password        remove the GROUP's password
- R, --restrict                restrict access to GROUP to its members
- M, --members USER,...      set the list of members of GROUP
- A, --administrators ADMIN,...  
                              set the list of administrators for GROUP

Except for the -A and -M options, the options cannot be combined.

```
gpasswd --delete user group
```

Be sure to log off and log back on for changes to take effect.

## Remove User from Group by Exclusion

<https://linuxhandbook.com/remove-user-from-group/>

First, list all the groups the user is member of using `id` command like this:

```
id -nG user_name
```

This will list all the groups of the user.

You can use the `usermod` command here with option `G`. With option `-G`, you specify which groups this user will belong to. If the user is currently a member of a group which is not listed, the user will be removed from the group.

```
sudo usermod -G group1,group2,group3 user_name
```

Do note that the group names must be separated by comma but there should be no whitespace between them.

## Change Password

<https://linuxize.com/post/how-to-change-user-password-in-linux>

The encrypted users' passwords, as well as other passwords related information, are stored in the `/etc/shadow` file.

### Change Your Password

As a regular user, you can only change your own password. The root user and users with sudo privileges can change another user's passwords and define how the password can be used or changed.

To change your own user's account password, run the `passwd` command without any arguments:

```
passwd
```

You will be prompted to enter your current password. If the password is correct, the command will ask you to enter and confirm the new password.

### Change Another User's Password

Only the root user and users with sudo access can change the password of another user account.

To change the password of another user account, run the `passwd` command, followed by the username. For example, to change the password of a user named `linuxize`, run the following command:

```
sudo passwd linuxize
```

You will be prompted to enter and confirm the new password:

## Logoff and Power Down - Shutdown

[How to Reboot Linux Using the Command Line \(lifewire.com\)](#)

<https://www.howtogeek.com/411925/how-to-reboot-or-shut-down-linux-using-the-command-line/>

**sudo shutdown -P now** Logs the current user out and powers down the machine.

### Shutdown Options

The **-H** (halt) option will take your computer down to the halt state but will not ask the hardware to power down. If you use this you will also have to **power off** the machine.

The **-P** (poweroff) is the default action . The computer is brought down to the halt state and is then powered off.

The **-r** (reboot) option will take your computer down to the halt state and then restart it.

The **-h** (halt and poweroff) option is the same as -P. If you use -h and -H together, the -H option takes priority.

The **-c** (cancel) option will cancel any scheduled shutdown, halt or reboot.

### The reboot, halt and poweroff Commands

These commands perform the action their name suggests. However, each of them will accept command line options to make any one of them perform a reboot, a halt, or a poweroff. But why confuse matters? These commands are best used at face value.

If you want to reboot now, use `reboot` . If you want to poweroff now, use `poweroff`, and if you want halt the system now, use `halt`.

These commands take immediate effect. If any of these commands are refused, precede them with `sudo`. But be aware, a refusal is usually because there are other users logged into the system that you're about to take offline.

### Which Command is Right For Me?

In multi-user environments using shutdown to perform these actions gives you more control. The facility to schedule shutdowns and reboots, and to alert users with a broadcast message will be invaluable in these cases. For a single-user computer, reboot and poweroff will probably meet your needs.

## pwd – Print Working Directory

**pwd** print working directory - shows you how to get to current directory from root -- The absolute path.

## mkdir – Make Directory

**mkdir** [option] directory\_name\_or\_path

**mkdir new\_dir** Creates 'new\_dir' in the current directory

**mkdir -p dir1/dir2/dir3/dir4** Create directory path. Create directories if needed.

## cd – Change Directory

**cd ~/** Go to Home Directory.

**cd path/of/the/dir/u/want/to/go** Move to the specified directory.

**cd ..** Go to the parent directory.

## rm – Remove Command

**rm** - remove.

**rm file\_name** Delete file.

**rm -r dir** Delete a directory recursively.

Options:

1. **-i (Interactive Deletion)**: Like in cp, the -i option makes the command ask the user for confirmation before removing each file, you have to press y for confirm deletion, any other key leaves the file un-deleted.

```
$ rm -i d.txt
```

rm: remove regular empty file 'd.txt'? y

2. **-f (Force Deletion)**: rm prompts for confirmation removal if a file is write protected. The -f option overrides this minor protection and removes the file forcefully.

```
rm -f e.txt
```

Note: -f option of rm command will not work for write-protect directories.

3. **-r (Recursive Deletion)**: With -r(or -R) option rm command performs a tree-walk and will delete all the files and sub-directories recursively of the parent directory. At each stage it deletes everything it finds. Normally, rm would not delete the directories but when used with this option, it will delete.

## mv – Move/Rename

**mv file newfile** rename *file* in *newfile*.

**mv file new/path** move file in the specified directory.

**mv file new/path/newfile** move file as newfile in the specified directory.

**mv -f** move without confirmation if overwriting.

## cp – Copy

**cp file newfile** copy file in newfile.

**cp file new/path** copy file in the specified directory.

**cp file new/path/newfile** copy file as newfile in the specified directory.

**cp -f** copy without confirmation if overwriting.

## ls – List file

[How to Use the ls Command to List Files and Directories on Linux \(howtogeek.com\)](http://howtogeek.com)

**ls** list content current directory.

**ls -l** List the files and directories in the current directory in long (table) format (It is recommended to use -l with ls for better readability).

**ls /other/path** list content of another dir.

**ls file** check if file is present in the current dir.

**ls -a** List all the files including the hidden ones (File names starting with a . are hidden files in Linux).

**ls -s** size - print the allocated size of each file, in blocks.

**ls -s -h** size - print the allocated size of each file, in blocks. File sizes are presented in human readable format (-h)

**ls -S** sort by file size, largest first

--sort=WORD sort by WORD instead of name: none (-U), size (-S), time (-t), version (-v), extension (-X)

**ls -ld dir-name** List information about the directory dir-name instead of its contents.

**ls -F** Appends a symbol at the end of a file name to indicate its type (\* means executable, / means directory, @ means symbolic link, = means socket, | means named pipe, > means door).

**ls -lt** List the files sorted by last modified time with most recently modified files showing at the top(remember -l option provides the long format which has better readability).

**ls -lh** List the file sizes in human readable format.

**ls -lR** Shows all subdirectories recursively.

**tree** Will generate a tree representation of the file system starting from the current directory.

## more / cat / tail – Display contents of file

- more file** display content of file bit by bit.
- cat file** display content of file all at once.
- tail file** display last 10 lines of file.
- tail -n 20 file** display last 20 lines of file.
- tail -f file** display last 10 lines of file each time file is updated.

## > < | – Operators

- cat file > newfile** redirect output of cat to newfile (overwrite if newfile exists, otherwise newfile is created).
- cat file >> newfile** append output of cat to newfile.
- command < file** redirect file into a command (e.g., a program).
- grep string | more** use the output of grep as input of command more.

## ? \* – Wildcards

- rm -rf \*** remove all files and dirs in the current dir.
- mv file\* /new/path** move all files whose name starts with *file* in new/path.
- rm -f file\_00?.com** ? stands for every character in that position.

## Directory Permissions

### [How to change directory permissions in Linux | Pluralsight](#)

To change directory permissions in Linux, use the following:

- `chmod +rwx filename` to add permissions.
- `chmod -rwx directoryname` to remove permissions.
- **`chmod +x filename`** to allow executable permissions.
- **`chmod -wx filename`** to take out write and executable permissions.
- Note that “**r**” is for read, “**w**” is for write, and “**x**” is for execute.

## Group and Owner Permissions

### How to Change Directory Permissions in Linux for the Group Owners and Others

The command for changing directory permissions for group owners is similar, but add a “g” for group or “o” for users:

- `chmod g+w filename`
- `chmod g-wx filename`
- `chmod o+w filename`
- `chmod o-rwx foldername`

To change directory permissions for everyone, use “u” for users, “g” for group, “o” for others, and “ugo” or “a” (for all).

- **`chmod ugo+rwx foldername`** to give read, write, and execute to everyone.
- **`chmod a=r foldername`** to give only read permission for everyone.

## File Permissions

<https://www.howtogeek.com/437958/how-to-use-the-chmod-command-on-linux/>

### [How to change directory permissions in Linux | Pluralsight](#)

To change directory permissions in Linux, use the following:

- `chmod +rwx filename` to add permissions.
- `chmod -rwx directoryname` to remove permissions.
- **`chmod +x filename`** to allow executable permissions.
- **`chmod -wx filename`** to take out write and executable permissions.

Note that “r” is for read, “w” is for write, and “x” is for execute.

`chmod <specification> filename`

**<specification>**      Change the file permissions.

u user

g group,

o other,

+ add permission

- remove

r read

w write

x execute.

**`chmod -R <specification> dir-name`** Change the permissions of a directory recursively. To change permission of a directory and everything within that directory, use this command.

**`chmod go+=r myfile`**      Add read permission for the owner and the group.

**`chmod a +rwx myfile`**      Allow all users to read, write or execute myfile.

**`chmod go -r myfile`**      Remove read permission from the group and others.

**`chown owner1 filename`**      Change ownership of a file to user owner1.

**`chgrp grp_owner filename`**      Change primary group ownership of file filename to group grp\_owner.

**`chgrp -R grp_owner dir-name`**      Change primary group ownership of directory dir-name to group grp\_owner recursively. To change group ownership of a directory and everything within that directory, use this command.

## grep – Find a string in files

grep [options] pattern [files]

Options Description

- c** This prints only a count of the lines that match a pattern
- h** Display the matched lines, but do not display the filenames.
- I** Ignores, case for matching.
- l** Displays list of a filenames only.
- n** Display the matched lines and their line numbers.
- v** This prints out all the lines that do not matches the pattern.
- e exp** Specifies expression with this option. Can use multiple times.
- f file** Takes patterns from file, one per line.
- E** Treats pattern as an extended regular expression (ERE).
- w** Match whole word.
- o** Print only the matched parts of a matching line, with each such part on a separate output line.
- A n** Prints searched line and *n* lines after the result.
- B n** Prints searched line and n line before the result.
- C n** Prints searched line and n lines after before the result.

**grep “string\_to\_search” file** search for the string in *file*.

**grep -R “string\_to\_search” \*** search the string in all files and directories.

**grep -c “string” file | nl** search string in file and return the number of lines containing string. The output of grep is suppressed by the flag -c

## Tar / zip / gzip – Archives

Options:

- c Creates Archive.
- x Extract the archive.
- f creates archive with given filename.
- t displays or lists files in archived file.
- u archives and adds to an existing archive file.
- v Displays Verbose Information.
- A Concatenates the archive files.
- z zip, tells tar command that create tar file using gzip.
- j filter archive tar file using tbzip.
- W Verify an archive file.
- r update or add file or directory in already existed .tar file

Examples:

- |                                |   |
|--------------------------------|---|
| zip/unzip file.zip             | create/extract compressed zip archives.   |
| gzip/gunzip file.gz            | create/extract compressed gzip archives.  |
| tar cvf file.tar *             | create non-compressed tar archived named file.tar of all the files and dirs in the current dir. |
| tar xvf file.tar               | extract tar archives.   |
| tar czvf file.tar.gz (or .tgz) | create compressed tar archives (same as gzip file.tar).   |
| tar xzvf file.tar.gz           | extract compressed tar archives (same as gunzip file.tar.gz)                                    |

## Keyboard Short Cuts

### Resources:

[Useful keyboard shortcuts \(ubuntu.com\)](https://ubuntu.com/keyboard-shortcuts)

[13 Keyboard Shortcuts Every Ubuntu User Should Know - It's FOSS \(itsfoss.com\)](https://itsfoss.com/13-keyboard-shortcuts-every-ubuntu-user-should-know/)

### Copy

**Ctrl+Shift+C**

### Paste

**Ctrl+Shift+V**

### Terminal Access

**Ctrl+Alt+T**

## Getting Around the Desktop

<b>Alt+F1</b> or the <a href="#">Super</a> key	Switch between the Activities overview and desktop. In the overview, start typing to instantly search your applications, contacts, and documents.
<b>Alt+F2</b>	Pop up command window (for quickly running commands). Use the arrow keys to quickly access previously run commands.
<b>Super+Tab</b>	<a href="#">Quickly switch between windows</a> . Hold down <b>Shift</b> for reverse order.
<b>Super+`</b>	Switch between windows from the same application, or from the selected application after <b>Super+Tab</b> .  This shortcut uses ` on US keyboards, where the ` key is above <b>Tab</b> . On all other keyboards, the shortcut is <b>Super</b> plus the key above <b>Tab</b> .
<b>Alt+Esc</b>	Switch between windows in the current workspace. Hold down <b>Shift</b> for reverse order.
<b>Ctrl+Alt+Tab</b>	Give keyboard focus to the top bar. In the Activities overview, switch keyboard focus between the top bar, dash, windows overview, applications list, and search field. Use the arrow keys to navigate.
<b>Super+A</b>	Show the list of applications.
<b>Super+Page Up</b> <b>Super+Page Down</b>	<a href="#">Switch between workspaces</a> .
<b>Shift+Super+Page Up</b> <b>Shift+Super+Page Down</b>	<a href="#">Move the current window to a different workspace</a> .
<b>Shift+Super+←</b>	Move the current window one monitor to the left.
<b>Shift+Super+→</b>	Move the current window one monitor to the right.
<b>Ctrl+Alt+Delete</b>	<a href="#">Show the Power Off dialog</a> .
<b>Super+L</b>	<a href="#">Lock the screen</a> .
<b>Super+V</b>	Show <a href="#">the notification list</a> . Press <b>Super+V</b> again or <b>Esc</b> to close.

## Common editing shortcuts

<b>Ctrl+A</b>	Select all text or items in a list.
<b>Ctrl+X</b>	Cut (remove) selected text or items and place it on the clipboard.
<b>Ctrl+C</b>	Copy selected text or items to the clipboard.
<b>Ctrl+V</b>	Paste the contents of the clipboard.
<b>Ctrl+Z</b>	Undo the last action.

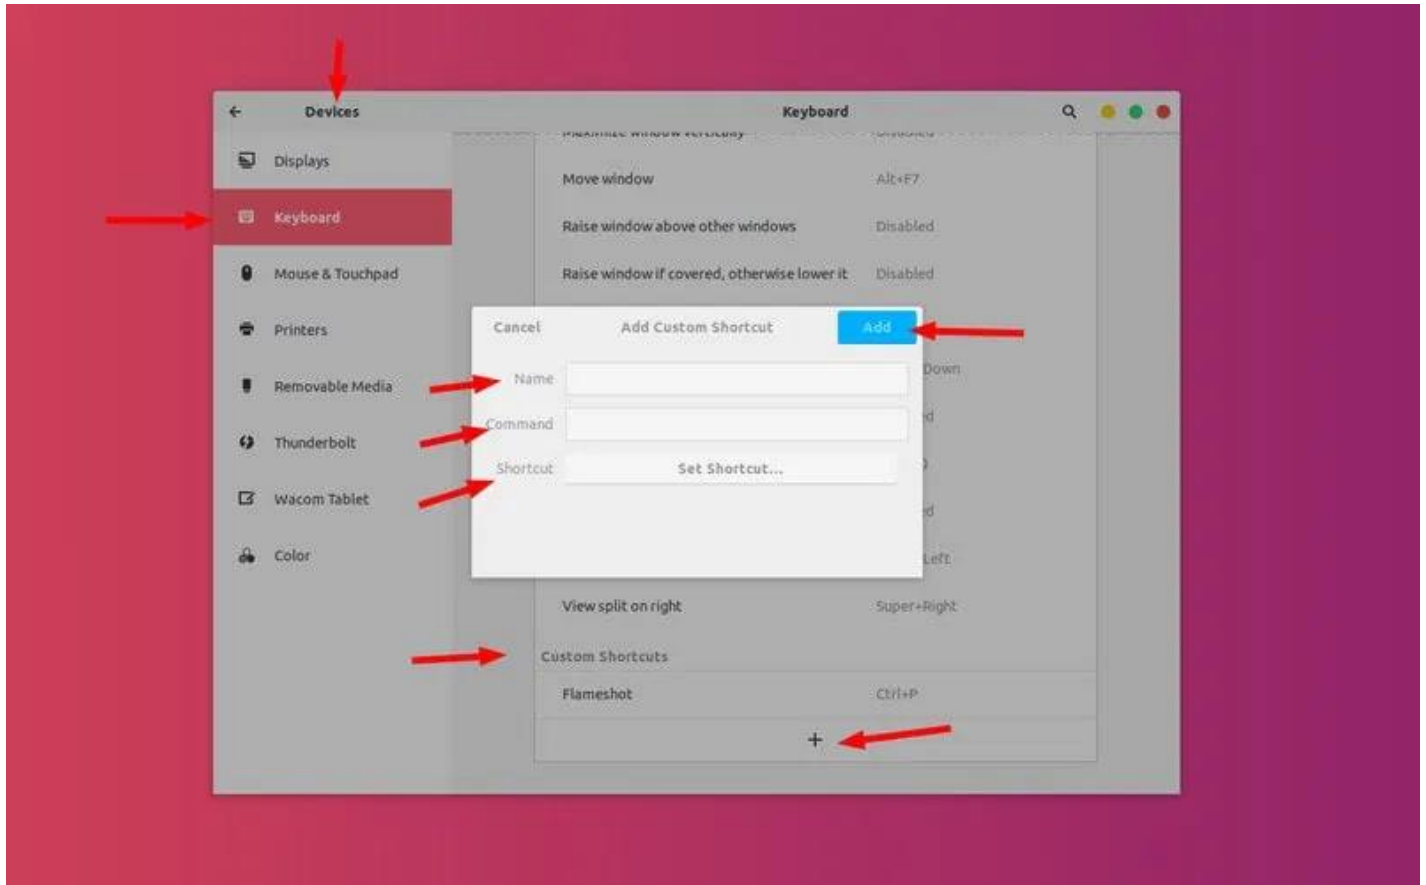

## Capturing from the screen

<b>Print Screen</b>	<a href="#">Take a screenshot.</a>
<b>Alt+Print Screen</b>	<a href="#">Take a screenshot of a window.</a>
<b>Shift+Print Screen</b>	<a href="#">Take a screenshot of an area of the screen.</a> The pointer changes to a crosshair. Click and drag to select an area.
<b>Ctrl+Alt+Shift+R</b>	<a href="#">Start and stop screencast recording.</a>

## Use Custom Keyboard Shortcuts in Ubuntu

You are not limited to the default keyboard shortcuts. You can create your own custom keyboard shortcuts as you like.

Go to Settings->Devices->Keyboard. You'll see all the keyboard shortcuts here for your system. Scroll down to the bottom and you'll see the Custom Shortcuts option.

## Networking

### Find IP Address of Current Machine

[How to Find IP Address in Linux Command Line \(linuxhandbook.com\)](https://linuxhandbook.com/how-to-find-ip-address-in-linux-command-line/)

**ip a** or **ip address**      Yields output that looks like this:

```
1: lo: mtu 65536 qdisc noqueue state UNKNOWN group default qlen 1000 link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00 inet 127.0.0.1/8 scope host lo valid_lft forever preferred_lft forever inet6 ::1/128 scope host valid_lft forever preferred_lft forever 2: wlp58s0: mtu 1500 qdisc mq state UP group default qlen 1000 link/ether 9c:b6:d0:d0:fc:b5 brd ff:ff:ff:ff:ff:ff inet 192.168.1.20/24 brd 192.168.1.255 scope global dynamic noprefixroute wlp58s0 valid_lft 5962sec preferred_lft 5962sec inet6 fe80::bf14:21e3:4223:e5e4/64 scope link noprefixroute valid_lft forever preferred_lft forever
```

The IP Address is **192.168.1.20**. The sub-net mask is **24**.

### Ping

```
ping [option] hostname or IP address
```

Press Ctrl-C to stop the pings.

[Linux Ping Command With Examples \(phoenixnap.com\)](https://phoenixnap.com/blog/linux-ping-command-with-examples/)

#### Limit Number of Ping Packets

To make the `ping` command automatically stop after it sends a certain number of packets, use `-c` and a number. This sets the desired amount of ping requests, as shown in this example:

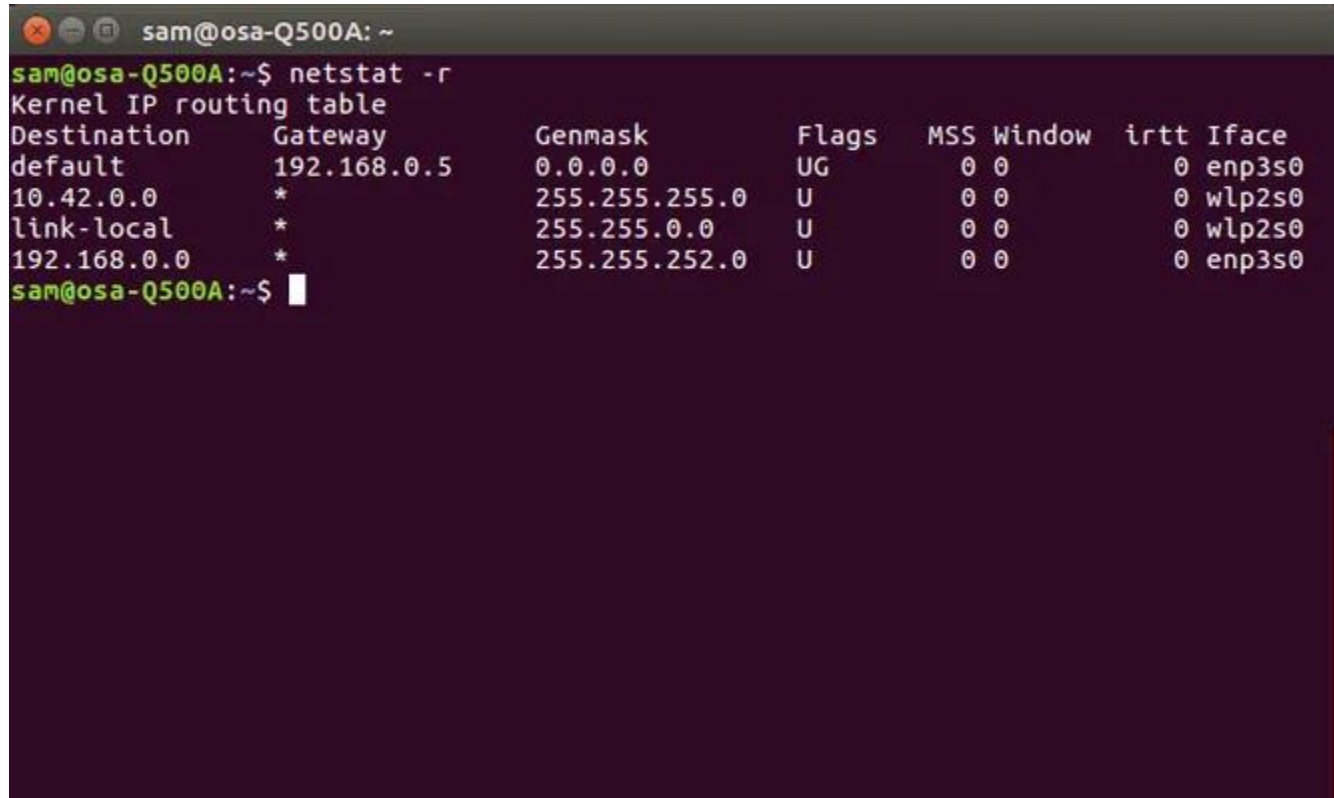

```
ping -c 2 google.com
```

## Netstat

Netstat command displays different information including open sockets and routing tables. Run netstat command alone to see a list of open sockets. Netstat has a ton of options.

Add the option `-r` to display information on the routing table.

A terminal window titled 'sam@osa-Q500A: ~' showing the command 'netstat -r' and its output. The output is titled 'Kernel IP routing table' and displays a table with columns: Destination, Gateway, Genmask, Flags, MSS, Window, irtt, and Iface. The table lists four entries: 'default' with gateway 192.168.0.5 and interface enp3s0; '10.42.0.0' with gateway \* and interface wlp2s0; 'link-local' with gateway \* and interface wlp2s0; and '192.168.0.0' with gateway \* and interface enp3s0.

```
sam@osa-Q500A:~$ netstat -r
Kernel IP routing table
Destination      Gateway         Genmask         Flags   MSS Window  irtt  Iface
default          192.168.0.5    0.0.0.0         UG        0  0        0 enp3s0
10.42.0.0        *              255.255.255.0   U         0  0        0 wlp2s0
link-local       *              255.255.0.0     U         0  0        0 wlp2s0
192.168.0.0      *              255.255.252.0   U         0  0        0 enp3s0
sam@osa-Q500A:~$
```

Add the option `-p` to display information of programs connected to the open sockets.

## Tcpdump

**Tcpdump** captures packets off a network interface and interprets them for you. It can be used to save entire packets for later inspection.

[illegible]

## Host

Command to find name to IP or IP to name in IPv4 or IPv6 and also query DNS records. Give it a domain name and you'll see the associated IP address. Give it an IP address and you'll see the associated domain name.

```
sam@osa-Q500A: ~  
sam@osa-Q500A:~$ host www.google.com.gh  
www.google.com.gh has address 197.251.230.30  
www.google.com.gh has address 197.251.230.53  
www.google.com.gh has address 197.251.230.19  
www.google.com.gh has address 197.251.230.44  
www.google.com.gh has address 197.251.230.49  
www.google.com.gh has address 197.251.230.34  
www.google.com.gh has address 197.251.230.27  
www.google.com.gh has address 197.251.230.15  
www.google.com.gh has address 197.251.230.29  
www.google.com.gh has address 197.251.230.38  
www.google.com.gh has address 197.251.230.57  
www.google.com.gh has address 197.251.230.59  
www.google.com.gh has address 197.251.230.23  
www.google.com.gh has address 197.251.230.45  
www.google.com.gh has address 197.251.230.42  
www.google.com.gh has IPv6 address 2a00:1450:4003:806::2003  
sam@osa-Q500A:~$ host www.linuxandubuntu.com  
www.linuxandubuntu.com has address 199.34.228.65  
sam@osa-Q500A:~$
```

## Tracepath

Tracepath traces the path of the network to the destination you have provided. It attempts to list the series of hosts through which your packets travel on their way to a given destination. It can be very handy when trying to determine the points of slowness in your connection path.

```
sam@osa-Q500A: ~  
sam@osa-Q500A:~$ tracepath linuxandubuntu.com  
1?: [LOCALHOST] pmtu 1500  
1: 192.168.0.5 1.449ms  
1: 192.168.0.5 1.407ms  
2: 41.66.205.225 8.040ms  
3: 80.231.76.186 19.278ms  
4: ix-pos-3-0-1.core4.LDN-London.as6453.net 113.871ms  
5: if-xe-0-1-3-0.tcore2.LDN-London.as6453.net 110.155ms  
6: ldn-b5-link.telia.net 131.220ms asymm 11  
7: ldn-bb3-link.telia.net 126.169ms asymm 10  
8: ash-bb4-link.telia.net 201.137ms asymm 9  
9: sjo-b21-link.telia.net 283.482ms asymm 10  
10: sjo-b21-link.telia.net 276.201ms  
11: sjo-b21-link.telia.net 278.856ms !H  
Resume: pmtu 1500  
sam@osa-Q500A:~$
```

## Ifconfig

This command is used to display IP Address, Hardware and MAC address. It is also used configure network interfaces. You can use it to activate or deactivate interfaces, assign an IP Address to the interface.

```
sam@osa-Q500A: ~  
sam@osa-Q500A:~$ ifconfig  
enp3s0    Link encap:Ethernet  HWaddr 60:a4:4c:09:c7:75  
          inet addr:192.168.2.55  Bcast:192.168.3.255  Mask:255.255.252.0  
          inet6 addr: fe80::a43e:bf65:9882:94fd/64 Scope:Link  
          UP BROADCAST RUNNING MULTICAST  MTU:1500  Metric:1  
          RX packets:201536 errors:0 dropped:0 overruns:0 frame:0  
          TX packets:59902 errors:0 dropped:0 overruns:0 carrier:0  
          collisions:0 txqueuelen:1000  
          RX bytes:76081100 (76.0 MB)  TX bytes:8243168 (8.2 MB)  
  
lo        Link encap:Local Loopback  
          inet addr:127.0.0.1  Mask:255.0.0.0  
          inet6 addr: ::1/128 Scope:Host  
          UP LOOPBACK RUNNING  MTU:65536  Metric:1  
          RX packets:2650 errors:0 dropped:0 overruns:0 frame:0  
          TX packets:2650 errors:0 dropped:0 overruns:0 carrier:0  
          collisions:0 txqueuelen:1  
          RX bytes:288876 (288.8 KB)  TX bytes:288876 (288.8 KB)

          TX packets:43530 errors:0 dropped:0 overruns:0 carrier:0
```

## Ifdown

Use **ifdown** device-name/interface name to bring an interface down by following a script (which will contain your default networking settings). Simply type **ifup** and you will get help on using the script.

```
sam@osa-Q500A: ~  
sam@osa-Q500A:~$ ifdown --help  
Usage: ifdown <options> <ifaces...>  
  
Options:  
-h, --help           this help  
-V, --version        copyright and version information  
-a, --all            process all interfaces marked "auto"  
--allow CLASS        ignore non-"allow-CLASS" interfaces  
-i, --interfaces FILE use FILE for interface definitions  
-X, --exclude PATTERN exclude interfaces from the list of  
                    interfaces to operate on by a PATTERN  
-n, --no-act         print out what would happen, but don't do it  
                    (note that this option doesn't disable mappings)  
-v, --verbose        print out what would happen before doing it  
-o OPTION=VALUE      set OPTION to VALUE as though it were in  
                    /etc/network/interfaces  
--no-mappings        don't run any mappings  
--no-scripts         don't run any hook scripts  
--no-loopback        don't act specially on the loopback device  
--force              force de/configuration  
--ignore-errors      ignore errors  
sam@osa-Q500A:~$
```

For example, typing: `ifdown eth0` Will bring eth0 down if it is currently up.

## ifup

Use ifdown device-name to bring an interface up by following a script (which will contain your default networking settings). Simply type ifup and you will get help on using the script.

```
sam@osa-Q500A: ~  
sam@osa-Q500A:~$ ifup --help  
Usage: ifup <options> <ifaces...>  
  
Options:  
  -h, --help                this help  
  -V, --version             copyright and version information  
  -a, --all                 process all interfaces marked "auto"  
  --allow CLASS             ignore non-"allow-CLASS" interfaces  
  -i, --interfaces FILE     use FILE for interface definitions  
  -X, --exclude PATTERN    exclude interfaces from the list of  
                           interfaces to operate on by a PATTERN  
  -n, --no-act              print out what would happen, but don't do it  
                           (note that this option doesn't disable mappings)  
  -v, --verbose             print out what would happen before doing it  
  -o OPTION=VALUE          set OPTION to VALUE as though it were in  
                           /etc/network/interfaces  
  --no-mappings             don't run any mappings  
  --no-scripts              don't run any hook scripts  
  --no-loopback             don't act specially on the loopback device  
  --force                   force de/configuration  
  --ignore-errors           ignore errors  
sam@osa-Q500A:~$
```

For example, typing: ifup eth0 Will bring eth0 up if it is currently down.

## Route

The **route** command is the tool used to display or modify the routing table.

```
sam@osa-Q500A: ~  
sam@osa-Q500A:~$ route  
Kernel IP routing table  
Destination      Gateway          Genmask          Flags Metric Ref    Use Iface  
default          192.168.0.5     0.0.0.0          UG        100    0      0 enp3s0  
10.42.0.0        *               255.255.255.0    U         600    0      0 wlp2s0  
link-local       *               255.255.0.0      U        1000    0      0 wlp2s0  
192.168.0.0      *               255.255.252.0    U         100    0      0 enp3s0  
sam@osa-Q500A:~$
```

You may add or delete routes or add a default gateway with the following commands.

```
route add -net 10.10.10.0/24 gw 192.168.0.1
```

```
route del -net 10.10.10.0/24 gw 192.168.0.1
```

```
route add default gw 192.168.0.1
```

## Nslookup

This command is used to find DNS related query.

A terminal window with a dark purple background. The title bar shows 'sam@osa-Q500A: ~'. The prompt is 'sam@osa-Q500A:~\$'. The command 'nslookup linuxandubuntu.com' has been entered. The output shows the server as 127.0.1.1 and the address as 127.0.1.1#53. Below that, it says 'Non-authoritative answer:' followed by 'Name: linuxandubuntu.com' and 'Address: 199.34.228.65'. The prompt is now 'sam@osa-Q500A:~\$' with a cursor.

```
sam@osa-Q500A: ~  
sam@osa-Q500A:~$ nslookup linuxandubuntu.com  
Server:      127.0.1.1  
Address:     127.0.1.1#53  
  
Non-authoritative answer:  
Name:   linuxandubuntu.com  
Address: 199.34.228.65  
  
sam@osa-Q500A:~$
```

## Dhclient

Use this command to release (-r option) your IP address and get a new one from your DHCP server.

A terminal window titled 'sam@osa-Q500A: ~' with a dark purple background. The window shows the following sequence of commands and output: 1. The user enters 'sudo dhclient -r'. 2. The system prompts '[sudo] password for sam:'. 3. The user enters 'sudo dhclient'. 4. The prompt returns to 'sam@osa-Q500A:~\$' with a cursor. The window has standard Linux window controls (close, maximize, and a third icon) in the top-left corner.

```
sam@osa-Q500A:~$ sudo dhclient -r
[sudo] password for sam:
sam@osa-Q500A:~$ sudo dhclient
sam@osa-Q500A:~$
```

## Whois

A whois query for Linux and Ubuntu will go something like this –

```
sam@osa-Q500A: ~  
sam@osa-Q500A:~$ whois linuxandubuntu.com  
  
Whois Server Version 2.0  
  
Domain names in the .com and .net domains can now be registered  
with many different competing registrars. Go to http://www.internic.net  
for detailed information.  
  
Domain Name: LINUXANDUBUNTU.COM  
Registrar: DOMAINSHYPE.COM, INC.  
Sponsoring Registrar IANA ID: 1660  
Whois Server: whois.domainshype.com  
Referral URL: http://www.domainshype.com  
Name Server: DNS1.HOSTGATOR.IN  
Name Server: DNS2.HOSTGATOR.IN  
Name Server: DNS3.HOSTGATOR.IN  
Name Server: DNS4.HOSTGATOR.IN  
Status: clientTransferProhibited https://icann.org/epp#clientTransferProhibited  
Updated Date: 01-nov-2016  
Creation Date: 20-nov-2014  
Expiration Date: 20-nov-2017  
  
>>> Last update of whois database: Mon, 07 Nov 2016 10:32:39 GMT <<<
```

### Get Version

#### Example-1

We can check the Linux Operating System (OS) info by running the below command

```
~$ cat /etc/os-release
```

#### Example-2

```
$ lsb_release -a
```

## Root Password

### Resources

<https://phoenixnap.com/kb/change-root-password-ubuntu>

[How to Change Root Password in Ubuntu Linux | Linuxize](#)

### Who Am I

Run this command to find your identity as recognized by the system.

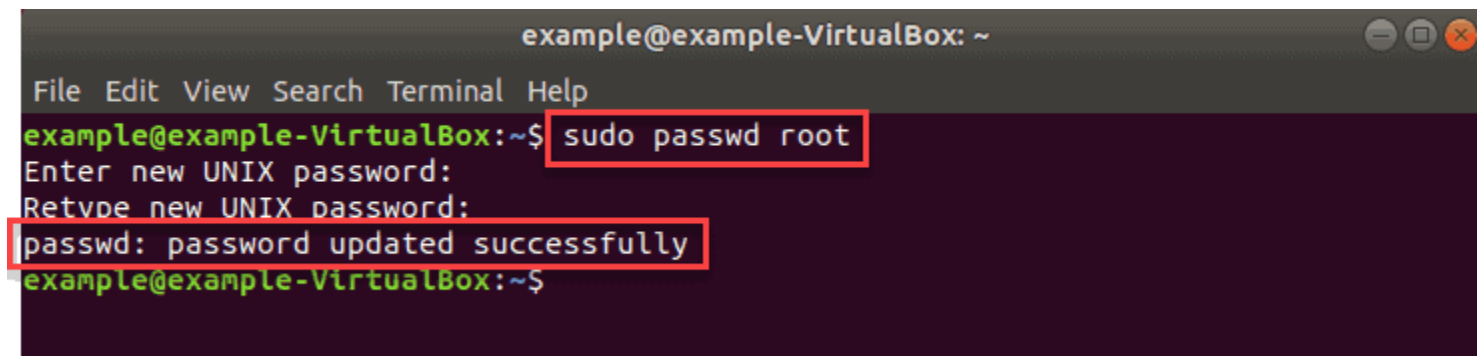

```
whoami
```

### Example-1: Changing Ubuntu Password in the Command Line

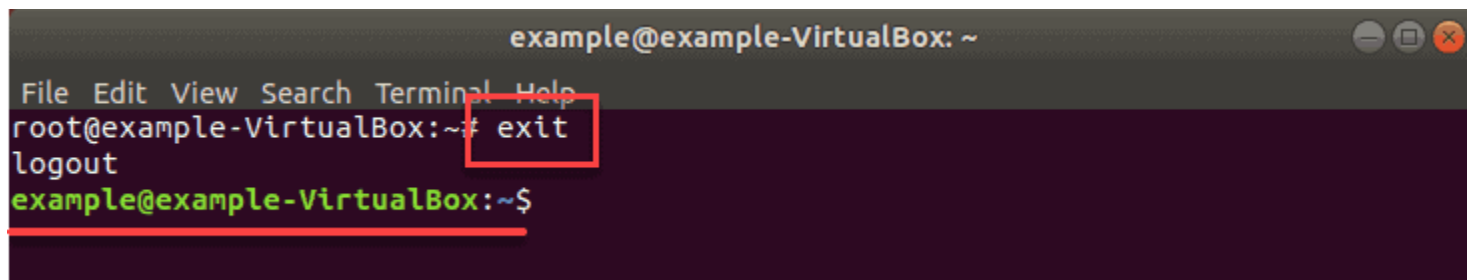

1. First, open the terminal using the keyboard shortcut CTRL+ALT+T.

2. Query for a password change by running the command:

```
sudo passwd root
```

A terminal window titled 'example@example-VirtualBox: ~' with a menu bar (File, Edit, View, Search, Terminal, Help). The prompt is 'example@example-VirtualBox:~\$'. The command 'sudo passwd root' is entered and highlighted with a red box. The output shows 'Enter new UNIX password:', 'Retype new UNIX password:', and 'passwd: password updated successfully', with the last line highlighted by a red box. The prompt returns to 'example@example-VirtualBox:~\$'.

```
example@example-VirtualBox: ~
File Edit View Search Terminal Help
example@example-VirtualBox:~$ sudo passwd root
Enter new UNIX password:
Retype new UNIX password:
passwd: password updated successfully
example@example-VirtualBox:~$
```

A terminal window titled 'example@example-VirtualBox: ~' with a menu bar (File, Edit, View, Search, Terminal, Help). The prompt is 'root@example-VirtualBox:~#'. The command 'exit' is entered and highlighted with a red box. The output shows 'logout' and the prompt returns to 'example@example-VirtualBox:~\$', which is underlined with a red line.

```
example@example-VirtualBox: ~
File Edit View Search Terminal Help
root@example-VirtualBox:~# exit
logout
example@example-VirtualBox:~$
```

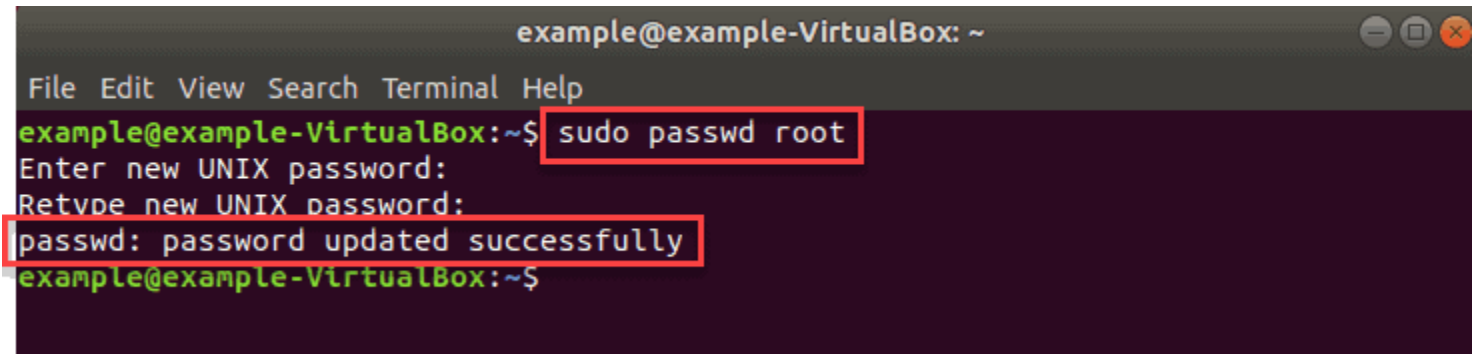

## Example 2: Change sudo Password with the passwd Command

An alternative is to switch to the root user and then run the passwd command to change the root password.

1. First, open the terminal (CTRL+ALT+T).
2. Switch to the root user with the command:

```
sudo -i
```

Type in your current password and hit Enter. The output you receive should show that you can now run commands as root.

```
example@example-VirtualBox: ~  
File Edit View Search Terminal Help  
example@example-VirtualBox:~$ sudo passwd root  
Enter new UNIX password:  
Retype new UNIX password:  
passwd: password updated successfully  
example@example-VirtualBox:~$
```

3. Next, change the password by running the command:

```
passwd
```

Type and retype a new password to verify the change.

4. After changing the password, log out of the root user with the command:

```
exit
```

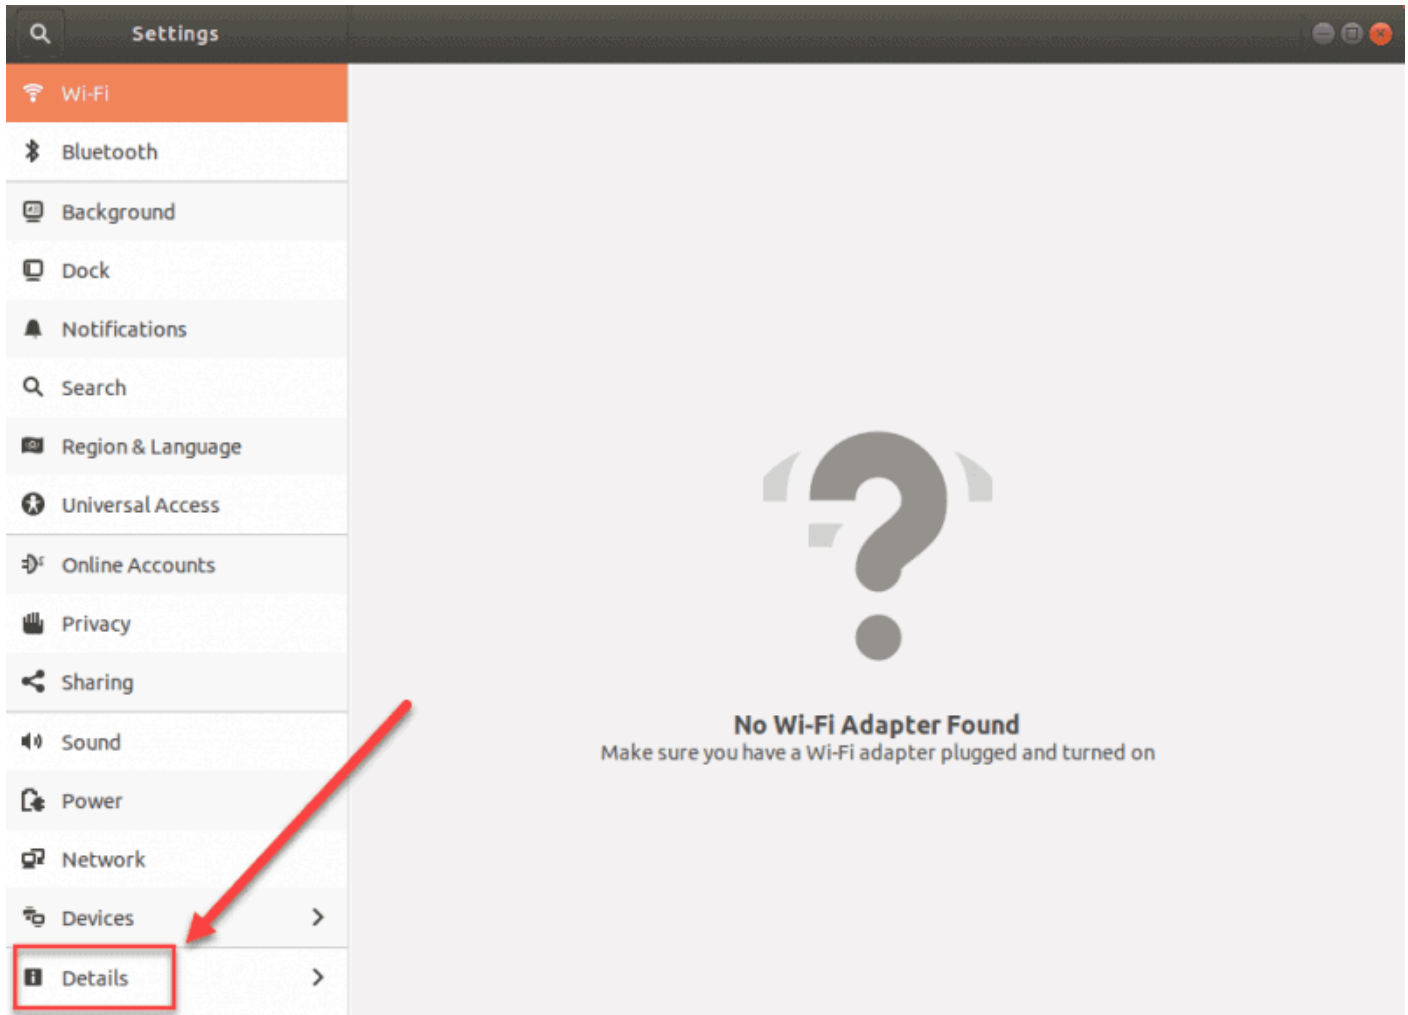

5. Exit out of the terminal with the same command:

```
exit
```

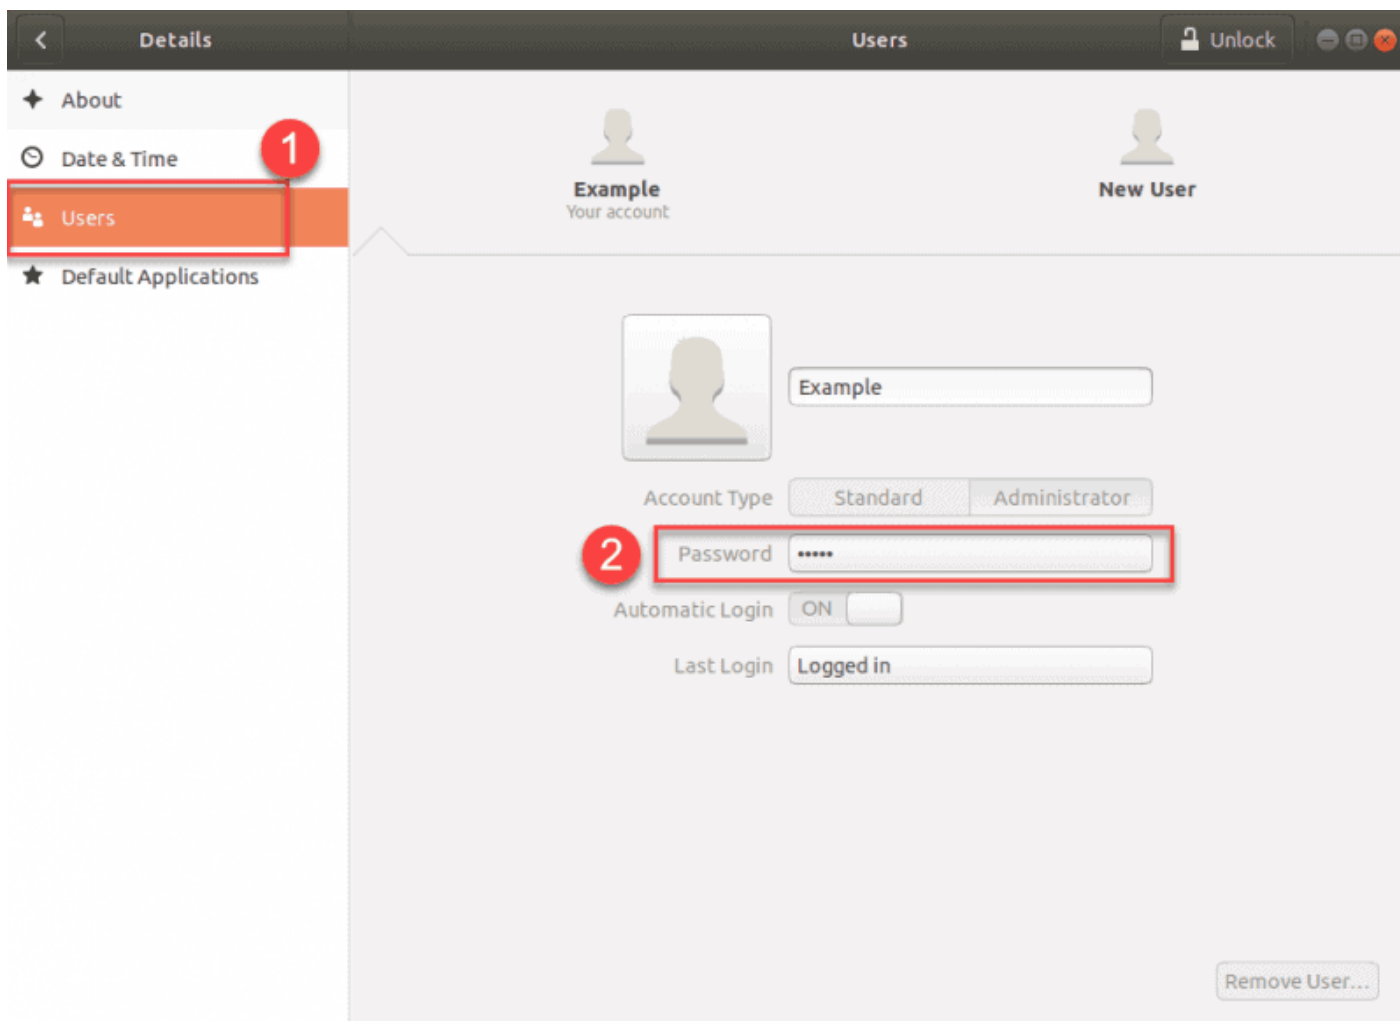

### Option 3: Changing Ubuntu Password Using GUI

To change the default root password in Ubuntu without using the terminal or any commands, use the graphical interface.

1. Open the Activities overview by pressing the Windows or Super key.
2. Type settings in the search bar and click on the Settings icon.
3. In Settings, click on the Details card (which is most likely the last one).

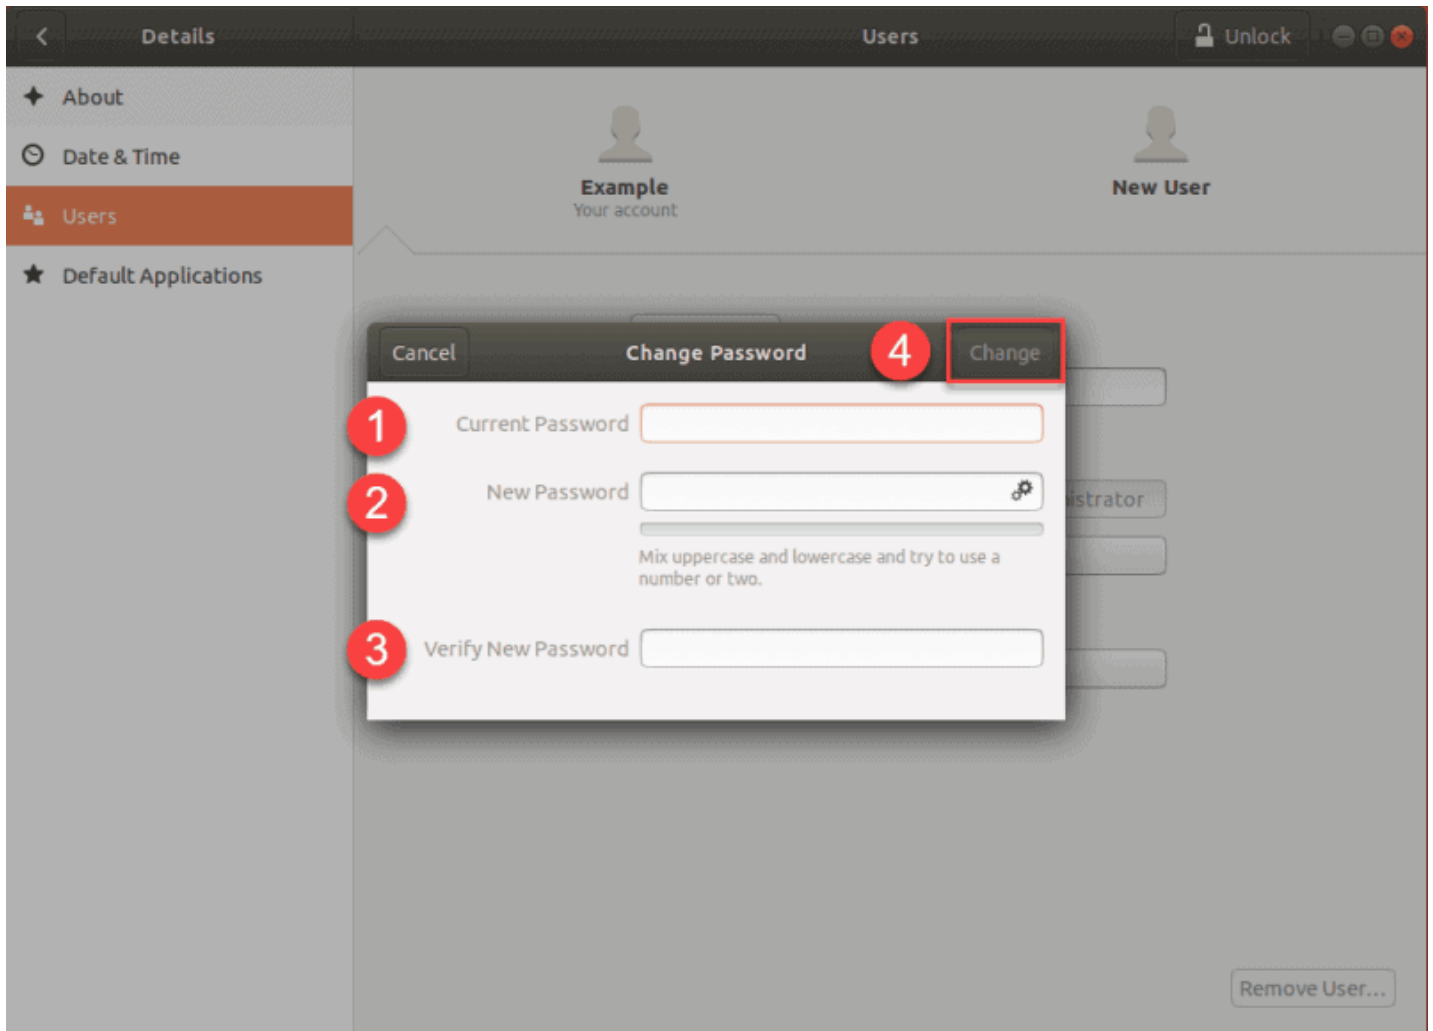

4. Next, click on Users. This lists all the details about the root user, including the password. Click on the password bar.

5. This will open a new Change Password pop-up. Type in your current root password, your new root password and verify the new password by retyping it.

6. Once you have filled in all the fields, click Change to confirm the changes.

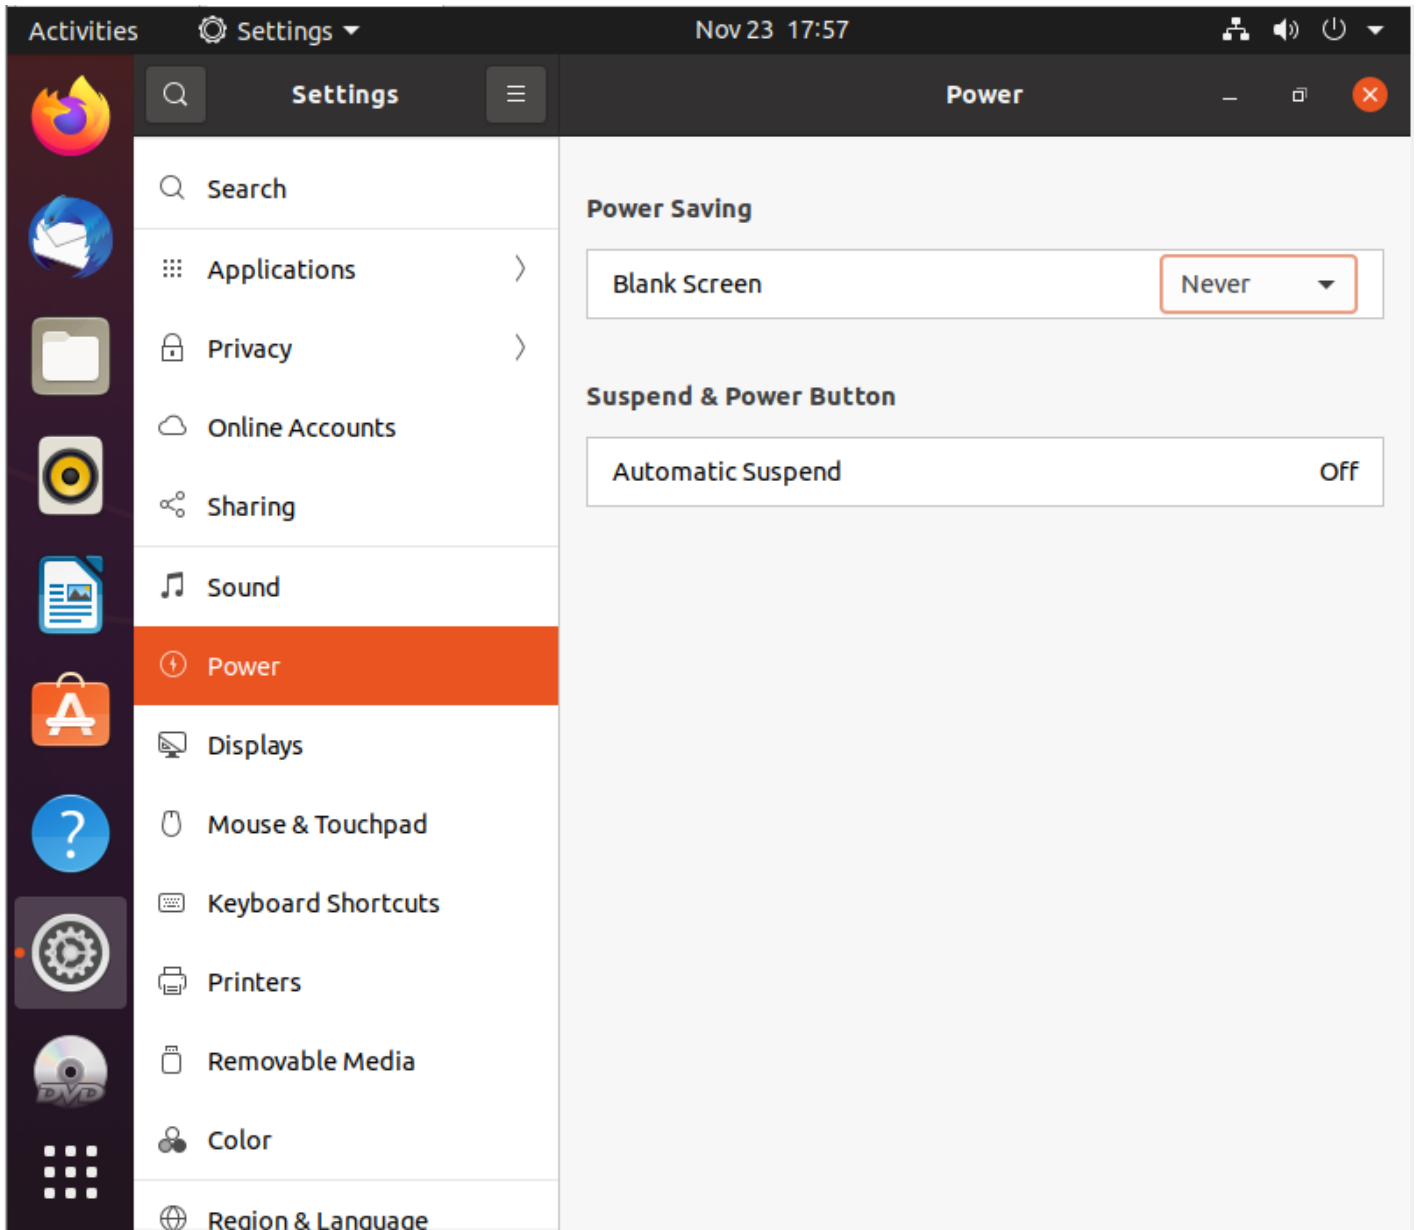

## Screen Time Out

### Resources

<https://askubuntu.com/questions/897066/how-do-i-set-the-screen-timeout>

### Control Time Out Through GUI

Select the System Settings from the icon located on the far right in your top panel. Once there select the **Power** settings. It will look as I've shown below. Change the "Power Saving" to **Never**, and change the "Suspend & Power Button" to "**Automatic Suspend – OFF**".

## Control Screen Lock Through Command Line Interface (CLI)

If you want to turn off the screen lock, run:

```
gsettings set org.gnome.desktop.screensaver lock-enabled false
```

### Shutdown

#### Command Syntax

Before going into specific ways to shut down your Linux system, you should understand the basic syntax of the shutdown command:

```
shutdown [options] [time] [message]
```

**[options]** define whether you want to halt, power-off, or reboot the machine.

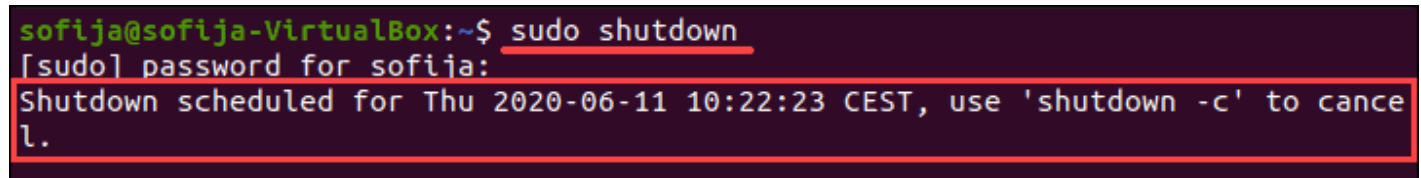

**[time]** specifies when you want the shutdown to perform.

**[message]** adds a message that announces the shutdown.

To use the shutdown command on Linux systems, a root user or a user with sudo privileges is required.

If you use the command without additional arguments, running `sudo shutdown` in a terminal window executes the shutdown in 60 seconds.

In the image below, see the output received after running the shutdown command.

A terminal window screenshot with a dark background. The prompt is 'sofiya@sofiya-VirtualBox:~\$'. The command 'sudo shutdown' is entered and highlighted with a red underline. The next line shows '[sudo] password for sofiya:'. The final line of output is 'Shutdown scheduled for Thu 2020-06-11 10:22:23 CEST, use 'shutdown -c' to cancel.' which is highlighted with a red rectangular box.

```
sofiya@sofiya-VirtualBox:~$ sudo shutdown  
[sudo] password for sofiya:  
Shutdown scheduled for Thu 2020-06-11 10:22:23 CEST, use 'shutdown -c' to cancel.
```

#### Shutdown With All Parameters

To view all parameters when shutting down the Linux system, use the following command:

```
sudo shutdown --help
```

The output displays a list of shutdown parameters, as well as a description for each.

```
sofiya@sofiya-VirtualBox:~$ sudo shutdown --help
[sudo] password for sofiya:
shutdown [OPTIONS...] [TIME] [WALL...]

Shut down the system.

Options:
  --help          Show this help
  -H --halt        Halt the machine
  -P --poweroff    Power-off the machine
  -r --reboot      Reboot the machine
  -h              Equivalent to --poweroff, overridden by --halt
  -k              Don't halt/power-off/reboot, just send warnings
  --no-wall        Don't send wall message before halt/power-off/reboot
  -c              Cancel a pending shutdown

See the shutdown(8) man page for details.
```

## How to Shut Down the System at a Specific Time

To schedule a shutdown, add the [time] argument and specify when you want it to take place. There are two ways to shut down the system at a specific time – using the absolute or relative time format.

The absolute time follows the format hh:mm and allows you to schedule a shutdown at a specified time. The command follows the syntax:

```
sudo shutdown hh:mm
```

For example, to require a shutdown at 7 AM in the morning, the command is:

```
sudo shutdown 07:00
```

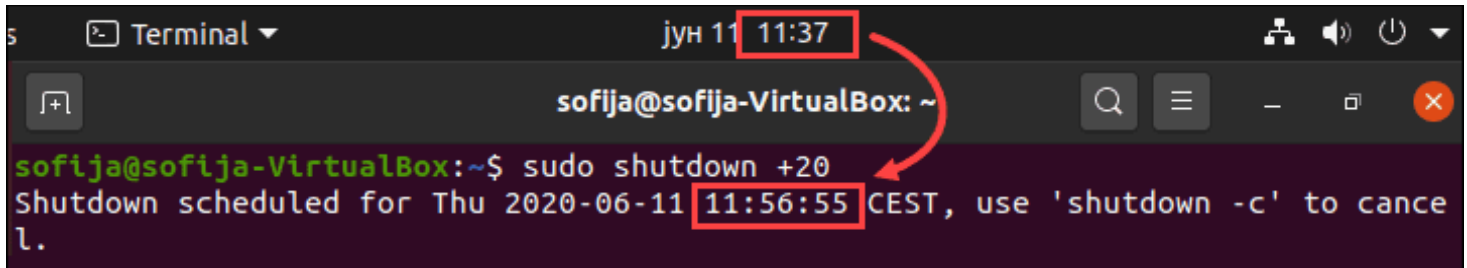

```
sofiya@sofiya-VirtualBox:~$ sudo shutdown 07:00
[sudo] password for sofiya:
Shutdown scheduled for Fri 2020-06-12 07:00:00 CEST, use 'shutdown -c' to cancel.
```

Alternatively, use the relative format (+m) and schedule a shutdown in a defined number of minutes from the time you run the command. In that case, the command syntax is:

```
sudo shutdown +m
```

To shut down the system in 20 minutes, run:

```
sudo shutdown +20
```

A terminal window titled "Terminal" with a dark background. The prompt is "sofija@sofija-VirtualBox: ~". The user has entered the command "sudo shutdown +20". The output is "Shutdown scheduled for Thu 2020-06-11 11:56:55 CEST, use 'shutdown -c' to cancel." A red box highlights the time "11:37" in the top right corner of the terminal window. A red arrow points from this box to the scheduled shutdown time "11:56:55" in the output text.

## How to Shut Down the System Immediately

As previously mentioned, running the shutdown command without any arguments prompts the system to shut down a minute after running the command. However, if you require an immediate shutdown, use:

```
sudo shutdown now
```

Another option would be to schedule a shutdown using the relative time format with the value 0, as in the command below:

```
sudo shutdown +0
```

## Restart

### Use the shutdown Command

Since powering off is one of the most basic functions of an operating system, this command should work for most distributions of Linux.

In a terminal window, type the following:

```
sudo shutdown -r
```

The `sudo` command tells Linux to run the command as an administrator, so you may need to type your password. The `-r` switch at the end indicates that you want the machine to restart.

### Alternative Option: Restart Linux with reboot Command

In the terminal, type:

```
reboot
```

Many Linux versions do not require administrator privileges to reboot. If you get a message that you do not have sufficient privileges, type:

```
sudo reboot
```

Your system should close out of all open applications and restart.

# ssh

## Resources

### Using an ssh-agent, or how to type your ssh password once, safely

[Using an ssh-agent, or how to type your ssh password once, safely. \(rabexc.org\)](http://rabexc.org)

You start an `ssh-agent` by running something like:

```
$ eval `ssh-agent`
```

in your shell. You can then feed it keys, with `ssh-add` like:

```
$ ssh-add /home/test/.ssh/id_rsa
```

or, if your key is in the default location, you can just:

```
$ ssh-add
```

`ssh-add` will ask your passphrase, and store your private key into the `ssh-agent` you started earlier. `ssh`, and all its friends (including `git`, `rsync`, `scp`...) will just magically use your agent friend when you try to ssh somewhere.

## Add Key To ssh-agent

### [Do I need a passphrase for my SSH key? - Linux Digest](#)

There is a tool that comes with OpenSSH, called ssh-agent. Ssh-agent will hold your private key within your login session. To enable ssh agent you will need to start it from the session you intend to using. It will output a couple of environment variables that need to be exported to your session. Use `eval` to catch these variables and automatically apply them:

```
max@max-desktop:~$ eval $(ssh-agent)
```

```
Agent pid 218387
```

Now you can add your key and passphrase to ssh-agent:

```
max@max-desktop:~$ ssh-add
```

```
Enter passphrase for /home/max/.ssh/id_rsa:
```

```
Identity added: /home/max/.ssh/id_rsa (max@max-desktop)
```

## How to use ssh-agent to cache your SSH credentials?

[Remember passphrases with ssh-agent — First published in fullweb.io issue #31 · GitHub](#)

Tired of always having to enter your SSH key passphrase when logging in to remote machines? Here comes ssh-agent. Enter the passphrase once and it will keep it in memory for you

### Using ssh-agent in your shell session:

```
$ ssh-agent
SSH_AUTH_SOCKET=/tmp/ssh-hZQhwQlxahPX/agent.1833; export SSH_AUTH_SOCKET;
SSH_AGENT_PID=1834; export SSH_AGENT_PID;
echo Agent pid 496;
```

### Copy/paste the 2 first lines from above:

```
$ SSH_AUTH_SOCKET=/tmp/ssh-hZQhwQlxahPX/agent.1833; export SSH_AUTH_SOCKET;
$ SSH_AGENT_PID=1834; export SSH_AGENT_PID;
```

### Register your key and enter your password for the last time of this session:

```
$ ssh-add .ssh/id_rsa
Enter passphrase for .ssh/id_rsa:
Identity added: .ssh/id_rsa (.ssh/id_rsa)
```

And now SSH auth will not ask you for the passphrase anymore

### BONUS: list your keys with:

```
$ ssh-add -l
```

[floudet](#) commented [on Jan 18, 2016](#)

You can also directly open a new shell session spawned by ssh-agent :

```
$ ssh-agent bash
```

The SSH\_AUTH\_SOCKET and SSH\_AGENT\_PID variables will already be set in the new shell session. It will spare you exporting them manually (step one and two above).

[ghost](#) commented [on Aug 9, 2018](#)

Save yourself the copy and paste job with eval.

```
eval $(ssh-agent)
```

## Enter SSH-Passphrase Once

[git - Enter SSH passphrase once - Ask Ubuntu](#)

## Permanently Add A Private Key With SSH Add

[How to permanently add a private key with ssh-add on Ubuntu? - Stack Overflow](#)

A solution would be to force the key files to be kept permanently, by adding them in your ~/.ssh/config file:

```
IdentityFile ~/.ssh/gitHubKey
IdentityFile ~/.ssh/id_rsa_buhlServer
```

If you do not have a 'config' file in the ~/.ssh directory, then you should create one. It does not need root rights, so simply:

```
nano ~/.ssh/config
```

...and enter the lines above as per your requirements.

For this to work the file needs to have chmod 600. You can use the command `chmod 600 ~/.ssh/config`.

If you want all users on the computer to use the key put these lines into /etc/ssh/ssh\_config and the key in a folder accessible to all.

Additionally if you want to set the key specific to one host, you can do the following in your ~/.ssh/config :

```
Host github.com
  User git
  IdentityFile ~/.ssh/githubKey
```

This has the advantage when you have many identities that a server doesn't reject you because you tried the wrong identities first. Only the specific identity will be tried.

## Not Stupid SSH Tricks: Automatic ssh-add

[Not Stupid SSH Tricks: Automatic ssh-add - Stuff... And Things... \(stuff-things.net\)](https://stuff-things.net/Not-Stupid-SSH-Tricks-Automatic-ssh-add-Stuff-And-Things/)

If you password protect your SSH keys (and you should) and you don't store those passwords in your macOS keychain or Linux equivalent (slightly paranoid, but not a bad idea), you have to add keys to [ssh-agent](#) with [ssh-add](#) before using them. Otherwise, you'll be prompted for the key's password on each use. This always bites me when doing deploys, I get prompted multiple times as the deploy process makes multiple SSH connections.

Fortunately, there's a simple fix.

All you need to do is add:

```
AddKeysToAgent yes
```

to your `.ssh/config`. Just as it says on the label, keys are automatically added to the SSH Agent when they are used. You'll be prompted for the password on its first use, no need to add it separately. This works not only with `ssh` itself, but with things like Git, that use SSH under the hood. Boom!

## Ubuntu Manual - AddKeysToAgent

[Ubuntu Manpage: ssh\\_config — OpenSSH SSH client configuration files](#)

AddKeysToAgent

Specifies whether keys should be automatically added to a running ssh-agent(1). If this option is set to "yes" and a key is loaded from a file, the key and its passphrase are added to the agent with the default lifetime, as if by ssh-add(1).

If this option is set to "ask", ssh will require confirmation using the SSH\_ASKPASS program before adding a key (see ssh-add(1) for details). If this option is set to "confirm", each use of the key must be confirmed, as if the -c option was specified to ssh-add(1). If this option is set to "no", no keys are added to the agent. The argument must be "yes", "confirm", "ask", or "no". The default is "no".

## The Ultimate Guide to SSH - Setting Up SSH Keys

[The Ultimate Guide to SSH - Setting Up SSH Keys \(freecodecamp.org\)](https://freecodecamp.org/The-Ultimate-Guide-to-SSH-Setting-Up-SSH-Keys/)

## Links Types

There are two types of links in Linux/UNIX systems:

### Hard links

You can think a hard link as an additional name for an existing file. Hard links are associating two or more file names with the same inode . You can create one or more hard links for a single file. Hard links cannot be created for directories and files on a different filesystem or partition.

### Soft links

A soft link is something like a shortcut in Windows. It is an indirect pointer to a file or directory. Unlike a hard link, a symbolic link can point to a file or a directory on a different filesystem or partition.

## How to Use the ln Command

**ln** is a command-line utility for creating links between files. By default, the ln command creates hard links. To create a symbolic link, use the -s (--symbolic) option.

The ln command syntax for creating symbolic links is as follows:

```
ln -s [OPTIONS] FILE LINK
```

Example:

```
sudo ln -s /opt/sublime_text/sublime_text /usr/bin/subl
```

If both the FILE and LINK are given, ln will create a link from the file specified as the first argument (FILE) to the file specified as the second argument (LINK).

If only one file is given as an argument or the second argument is a dot (.), ln will create a link to that file in the current working directory . The name of the symlink will be the same as the name of the file it points to.

By default, on success, ln doesn't produce any output and returns zero.

## Creating Symlink To a File

To create a symbolic link to a given file, open your terminal and type:

```
ln -s source_file symbolic_link
```

Replace source\_file with the name of the existing file for which you want to create the symbolic link and symbolic\_link with the name of the symbolic link.

The `symbolic_link` parameter is optional. If you do not specify the symbolic link, the `ln` command will create a new link in your current directory:

In the following example, we are creating a symbolic link named `my_link.txt` to a file named `my_file.txt`:

```
ln -s my_file.txt my_link.txt
```

To verify that the symlink was successfully created, use the `ls` command:

```
ls -l my_link.txt
```

The output will look something like this:

```
lrwxrwxrwx 1 linuxize users 4 Nov 2 23:03 my_link.txt -> my_file.txt
```

The `l` character is a file type flag that represents a symbolic link. The `->` symbol shows the file the symlink points to.

## Creating Symlinks To a Directory

The command for creating a symbolic link to a directory is the same as when creating a symbolic link to a file. Specify the directory name as the first parameter and the symlink as the second parameter.

For example, if you want to create a symbolic link from the `/mnt/my_drive/movies` directory to the `~/my_movies` directory you would run:

```
ln -s /mnt/my_drive/movies ~/my_movies
```

## Overwriting Symlinks

If you try to create a symbolic link that already exists, the `ln` command will print an error message.

```
ln -s my_file.txt my_link.txt
```

```
ln: failed to create symbolic link 'my_link.txt': File exists
```

To overwrite the destination path of the symlink, use the `-f` (`--force`) option.

```
ln -sf my_file.txt my_link.txt
```

## Removing Symlinks

To delete/remove symbolic links use either the unlink or rm command.

The syntax of the unlink is very simple:

```
unlink symlink_to_remove
```

Removing a symbolic link using the rm command is the same as when removing a file:

```
rm symlink_to_remove
```

No matter which command you use, when removing a symbolic link **do not** append the / trailing slash at the end of its name.

If you delete or move the source file to a different location, the symbolic file will be left dangling (broken) and should be removed.

## Conclusion

To create a symbolic link in Linux use the ln command with the -s option.

For more information about the ln command, visit the **ln man** page or type **man ln** in your terminal.

## Time Zone Configuration

[4 Ways to Change the Timezone in Linux - wikiHow](#)

<https://linuxize.com/post/how-to-set-or-change-timezone-in-linux/>

**date** Displays date, time and time zone.

Example: Sun 23 May 2021 12:20:41 AM PDT

**date -u** Displays UTC Time

**ls -l /etc/localtime** Identifies current timezone by name

**man date** Displays more date formats and information.

**timedatectl** Displays time, time zone and indicates whether the NTP time synchronization service is active.

### Set Your Time Zone

# The following command will list all available timezones.

```
timedatectl list-timezones
```

# Choose your time zone from list generated by last command.

# Then run this command will set the new time zone.

```
sudo timedatectl set-timezone <your_time_zone>
```

# Example

```
sudo timedatectl set-timezone America/New_York
```

# Verify the timezone change.

```
timedatectl
```

After you set the time zone. Log out and log back on to verify the timezone change.

## Install NTP

If NTP is not installed, install it. Read this first.

[How to sync time on Ubuntu 20.04 Focal Fossa Linux - LinuxConfig.org](https://linuxconfig.org/how-to-sync-time-on-ubuntu-20.04-focal-fossa-linux)

Run this command to determine if NTP is active:

```
timedatectl
```

If NTP is 'Active' it is recommended that you stop here and skip this step. Do NOT Install NTP.

```
sudo apt install ntpdate
```

After installation, link to a server clock for continued updates.

```
ntpdate server link && hwclock -w
```

Make sure to enter the link to the website in place of **server link**.

## Who Am I

Run this command to find your identity as recognized by the system.

```
whoami
```
